Attorney Docket No. 04329.2683

**ATTACHMENT: SUBSTITUTE ABSTRACT**

A semiconductor device includes a plurality of cell arrays, a selection control circuit to generate and to output a selection control signal. An array selection circuit generates internal address signals on the basis of an external address signal and the selection control signal. The array selection circuit outputs the internal address signals to the plurality of cell arrays to select ones of the cell arrays. A sales method for selling semiconductor devices includes presenting function-related information and price-related information on partially good semiconductor devices to client terminals and prompting the client terminals to provide purchase/non-purchase information and determining the possibility of successful transactions on the basis of the purchase/non-purchase information. A sales system for selling semiconductor devices uses the sales method and a sales program product for causing a computer system to sell semiconductor devices using the sales method.
